LETTERS TO THE EDITOR

Letters intended for publication should be a maximum of 500 words, 10 references, and one table or figure, and should be sent to the editor at the address given on the inside front cover. Those responding to articles or correspondence published in the journal should be received within six weeks of publication.

Whose standard is it, anyway?

EDITOR—In their recent article in Tobacco Control Bialous and Yach* create the impression that international standards for the machine smoking of cigarettes were foisted on the smoking public unilaterally by the tobacco industry by its influence on the International Organization for Standardization (ISO) through control of CORESTA (Centre de Co-operation pour les Recherches Scientifiques au Tabac). They also allege, inter alia, that the tobacco industry (has, through CORESTA, changed the methodology in order to produce lower smoke yield values to get round the European “tar” ceiling directives, and (2) misleads the public by developing lower “tar” cigarettes to cheat the smoking machine, and then makes unjustified health claims about them. (“Standards” are documented agreements containing technical specifications or concise criteria to be used consistently as rules guidelines.)

In their article, Bialous and Yach* concentrated predominantly on a few highly selective quotes from internal tobacco company documents. They appear not to have consulted much of the very large volume of scientific literature published on the subject. When this information is taken into account it becomes obvious that the very narrow and restricted literature base of Bialous and Yach’s analysis has resulted in them making factual errors, drawing wrong conclusions and writing inaccurate statements on many aspects of the subject.

A review of the published literature on the subject shows clearly that the broad facts are as follows:

(1) Techniques relevant to the machine smoking of cigarettes were developed and refined throughout the 20th century.1 The first standard was specified by the Federal Trade Commission (FTC), a US federal government agency, in 1966 and first used to test cigarettes in 1967.2 The CORESTA recommended method, similar in many respects to that of the FTC, was developed after the FTC standard and was published in 1969.3

(2) There were small differences in the details of the smoking machine procedures in the various standard methods developed by the FTC and subsequently CORESTA, ISO and authorities in the UK, Germany, Canada and elsewhere between 1969 and the late 1970s.4 These differences resulted in about a 10% difference in the “tar” yield of the same cigarette measured by authorities in Britain and Germany, for example. By the late 1980s it was recognised that this situation was unacceptable in view of pending European directives which specified “tar” ceilings for all cigarettes sold in member states across Europe from 1993. Consequently, the differences in methodology were harmonised in a common ISO standard method in 1991, developed following a considerable amount of inter laboratory comparisons of the developing methodology undertaken within CORESTA across 29 laboratories from 15 countries.5 This revised standard method is now used in all countries except the USA where the slightly different FTC method still continues to be used, and in Japan where some minor differences are used in their national standard. Changing to the ISO standard in the early 1990s, “tar” yields determined in the UK, for example, decreased by up to 0.5 mg while “tar” yields in Canada, for example, increased by up to 3 mg for some brands.

(3) The purpose of the smoking machine standards is to determine the “tar”, nicotine, and carbon monoxide content of cigarette smoke when the cigarette is smoked under precisely defined conditions, and hence to allow a comparison of the yields from different cigarettes. Such yields are not predictive of the yields humans obtain when smoking, nor were they ever expected to be so, since no two smokers smoke exactly the same nor does a smoker smoke a cigarette the same way on every occasion. This purpose has been stated consistently many times, originally by the FTC in 1967,7 and subsequently in the scientific literature, published by the tobacco industry and health/regulatory authorities, over the last 35 years, e.g.

(4) Compensation by smokers when switching to a low “tar” cigarette has been discussed in the scientific literature for 40 years. The phenomenon was first published by the tobacco industry and tobacco industry scientists have published books and papers on the subject, e.g.8 9 10 The available evidence, albeit limited, indicates that compensation is partial in the short term (up to a few weeks), and that smokers switching from a higher to a lower “tar” yield cigarette do generally obtain a reduction in smoke delivery.11

(5) Since the 1950s numerous health scientists have advocated that lower “tar” cigarettes should be developed in the grounds that they may represent a less hazardous form of smoking, e.g.12 13 14 15 Health authorities have consistently advised smokers to quit, but for those who choose to continue to smoke that they should smoke “light” cigarettes, e.g.16 17 18 19 The tobacco industry has responded to these health authorities by developing cigarettes with lower “tar” but has also followed public health advice by not advertising lower “tar” cigarettes as safe cigarettes.

International Standard) will be published as an international standard with no changes other than editorial. What Bialous and Yach apparently fail to appreciate is that the ISO approval process leading up to the DIS stage involved a development period of at least four years and multiple balloting stages (opportu-
nities) for significant amendments. For example, balloting at the previous committee draft stage (ISO/TC 126 N 537, July 1995) generated nine pages of comments from 12 countries. The 1997 CORESTA minutes reflect only that at the DIS stage in the over-
all ISO process, no changes had been requested by ISO members other than those of an editorial nature.

Secondly, Bialous and Yach made a compound assertion, that “CORESTA works with ISO directly or that CORESTA works through one of ISO’s member bodies”. CORESTA does have a liaison member status with ISO, but does not work with any of ISO’s member bodies.

Lastly, Bialous and Yach assert “CORESTA resists any interference with its processes and makes efforts to keep overall control of the situation and the outcomes of ISO meetings”. Offered as support is a matter concerning updates to the ISO smoking methods. Again, an egregious misinterpretation has resulted. A CORESTA working group and the British Standards Institution (BSI) independently prepared editorial commentary on similar issues within the text of the ISO smoking methods. Writing to refer to the ISO process, CORESTA postponed an update to the existing CORESTA methods, instead wishing to wait for ISO to finish their deliberations.

A consequence of misappropriation, Bialous and Yach offer examples that do not support their contention. Rather to the contrary, these examples serve as testament to the pro-
propriety of the CORESTA-ISO relationship.

We look forward to a continued dialogue in the area of standardisation of tobacco products.

FRANCOIS JACOB
Secretary General, CORESTA
11 rue du Quatre Septembre, 75002 Paris, France
coresta.fjo@masanod.fr

Author’s reply

Editor—Mr Jacob and Dr Baker’s criticisms of our paper most likely indicate an incomplete reading of it. We believe our paper reached its point also made by Dr Baker. Recent literature and health authorities’ recommendations regarding “lower” tar and nicotine cigarettes show that switching to lower yields is no longer perceived as an effective means of addressing tobacco related morbidity and mortality.12 Several countries and the European Union have already banned or are moving to ban the utilisation of labels such as “mild” and “lights” based on scientific and tobacco industry documents. In many countries these labels are mislead the public into thinking these cigarettes are safer.13,14

Indeed, a 1977 British American Tobacco (BAT) document states that work in this area should be directed towards providing consumer reassurance about cigarettes and the smoking habit. This can be provided in different ways, for example, by claiming low deliveries, by the perception of low deliveries, and by the perception of “mildness”. Furthermore, advertising for low delivery or traditional brands should be constructed in ways so as not to provoke anxiety about health, but also to enable the smoker to feel assured about the habit and confident in maintaining it over time.15

We do not suggest “impropriety in CORESTA’s involvement” since, as per the ISO definition, the tobacco industry is entitled to participate in the process. However, we question the adequacy of having tobacco interests being the sole provider of scientific evidence in the area of tobacco products standardisation methods. We question CORESTA’s involvement as much as the lack of involvement from other interested parties (for example, health and consumer groups) as well as whether or not the ISO is fulfilling its aim of protecting the health and safety of consumers of tobacco products.

Mr Jacob’s assertion that the “majority of worldwide tobacco science expertise resides within the tobacco industry should come as surprise to no one” is correct. However, recent litigation has shown that this expertise has not been used to benefit the health and safety of the consumers of tobacco products.16,17 It is also no surprise that many of the tobacco industry experts “find themselves involved in CORESTA and ISO TC-126 activities”, but it is unacceptable that these experts only join those participating in these activities.

As for the three specific areas of criticism in Mr Jacob’s letter:

(1) From the description of the ISO standards approval process, the majority of work is done at the Technical Committee (TC) level, and final approval of a DIS (Draft International Standard) is by the TC as well. In the case of TC 126, with a majority of members representing the tobacco industry, and CORESTA being the organisation conducting the work on the proposed standards, amendments are referred back to the TC and to CORESTA. In the example offered, ISO/DIS 11454 reference 34 in our paper describes some of these comments and how they represent the tobacco industry’s perspective.

(2) We saw no evidence that CORESTA accepts outsiders’ input in preparing standards forwarded to ISO, but it is clear that they want to maintain “CORESTA methods and ISO standards . . . close or identical.”18 The following quote from the same document addresses how CORESTA planned to deal outside participation (by par-
ticipating in the validation stage, not in the development, of a measurement method).

We appreciate the opportunity to address these comments, and Mr Jacob’s offer for a continued dialogue in the area of standardisation of tobacco products.

Desire to stop smoking among intermittent and daily smokers: a population-based study

EDITOR—An important fraction of all smokers are intermittent, non-daily smokers, and the proportion of intermittent smokers may even be rising. Intermittent smokers are younger and have a higher educational and occupational status than daily smokers. Some intermittent smokers are either in the uptake phase of smoking, or are preparing for smoking cessation. However, intermittent smoking can also be a long term behaviour. Intermittent smokers are more likely than daily smokers to have a strong intention to quit smoking. They are also more likely to actively start the process of smoking cessation. Intermittent smokers probably also suffer less severe withdrawal symptoms during cessation attempts than do daily smokers and, therefore, have a greater potential for success. Intermittent smokers perceive quitting as not being very difficult. However, there are no studies concerning the prevalence of the desire to stop smoking among intermittent compared to daily smokers. The public health survey in Malmö 1994 is a cross sectional study. A total of 5600 individuals born in 1913, 1923, 1933, 1943, 1953, 1963, 1968, and 1973 were randomly selected from the general Malmö population and interviewed by a postal questionnaire in the spring of 1994. In each age group, 700 participants (350 men and 350 women) were interviewed. The participation rate was 71%. The desire to stop smoking item, “Do you want to stop smoking?”, had two alternative answers, “yes” and “no”, and the item was dichotomised accordingly. The smoking item contained four alternatives: never smoked, stopped smoking, daily smoker, and intermittent (non-daily) smoker. The sex differences in daily smoking, intermittent smoking, never smoked, and stopped smoking were calculated using t tests (results only presented in text). The proportions of daily and intermittent smokers that report a desire to stop smoking were also calculated with t tests (results only presented in text). The proportions of daily and intermittent smokers that express desire to stop smoking were calculated separately using logistic regression in order to analyse associations between sociodemographic variables and desire to stop smoking (table 1). The SPSS software package was used. A total of 56.4% of all male and 59.9% of all female smokers (both daily and intermittent) had expressed a desire to stop smoking (p < 0.001). The proportion of daily smokers was 24.5% among men and 23.7% among women (p < 0.001). Men were more likely than women to express a desire to stop smoking to the same extent. In contrast, intermittent smokers born abroad had expressed a desire to stop smoking to a much higher extent than the group born in Sweden. No significant differences between the educational status groups and smoking were observed for either daily or intermittent smokers. Non-participation is not likely to have produced serious selection bias. There was a good concordance between the register census data concerning foreign origin and the general educational level of the Malmö population. There is also the possibility of bias from self reported data. Although self reporting of desire to stop smoking is the only conceivable way to assess desire to stop smoking, it is subjective and may even reflect a person’s general perception of health. However, this fact works probably not bias the systematic differences between intermittent and daily smokers reported in this study. The proportion of all smokers that express a desire to stop smoking is very similar to the results of other studies. The results may seem surprising, given the fact that other studies have reported that some intermittent smokers may be former regular smokers in the process of smoking cessation, and that these studies have also reported a stronger intention to quit and a greater likelihood of having recently attempted to quit among intermittent smokers. However, the proportion of reports of an intentional desire to stop smoking seems to be much lower among intermittent than among daily smokers, and this finding strengthens the conclusion of other studies that a substantial fraction of all intermittent smokers are long term intermittent smokers and others are in the uptake phase of smoking. The conclusion that a higher proportion of daily smokers than intermittent smokers report a desire to stop smoking was only 20.4% of male and 14.3% of female intermittent smokers that expressed a desire to stop smoking (p < 0.001 when comparing daily and intermittent smokers among both men and women). Pomerleau and Pomerleau have stressed that nicotine has a variety of effects that may be directly reinforcing, even in the absence of dependence. Specific benefits of smoking

have been documented in cognitive and psychomotor performance. The smoking of intermittent smokers may be motivated by these effects. The results further support the notion that intermittent smokers are a specific group of smoking with smoking cessation characteristics that differ from the characteristics of daily smokers.

On-line teen smoking cessation: what’s porn got to do with it?

EDITOR—As part of our research on adolescent smoking, we conducted a search of the internet for on-line support for teen smoking cessation. We searched google.com using the words “teen quit smoking” (without quotation marks) which resulted in hundreds of potential links. In order to narrow the search to more specific tobacco-related sites, we used an advanced exact-phrase search of the key words “teen quit smoking” (with quotation marks) on the same search engine. To our amazement, seven out of the top 20 sites (35%) were teen pornography links. The phrase “teen quit smoking” was deliberately placed among the descriptors for each of these seven pornography links. On further review of several of these sites, this resulted in on-line smoking cessation material or links to actual cessation sites. Although we are unsure why this phrase would be placed among the descriptors for pornography sites, it raises concern about a teenager’s ability to find legitimate on-line cessation support. This unexpected placement of “teen quit smoking” potentially encourages teenagers to access on-line pornography, an activity that certainly would be discouraged by many proponents of teen smoking cessation. Fortunately, the same search strategies did not yield the same results with other popular internet search engines. Health educators need to be aware of this potential problem, as more and more teenagers are encouraged to access the internet for smoking cessation support and other health related information.

Smoking in movies in 2000 exceeded rates in the 1960s

EDITOR—Smoking in movies has been linked to increased smoking among teens.1 We have previously published data from 1960 through 1997 that shows that smoking fell from the 1960s through the 1980s, then increased during the 1990s.2 We used similar methods (analysis of a random sample of five of the top 20 grossing US films each year) to extend the data set through 2000 (fig 1).

We conducted a regression analysis of these data by filling a quadratic equation in time to the amount of tobacco use per hour. The equation, smoke/hour = 801 − 0.405 (± 0.0044, p = 0.004) year + 0.0124 (± 0.0032, p = 0.004) year², confirms that, after falling during the early part of this period, smoking

www.tobaccocontrol.com

is now increasing significantly. Based on this regression equation, on average there were 7.3 instances of tobacco use per hour in films in 1960 compared with 10.9 in 2000.

The messages continue to reflect tobacco industry marketing themes of glamour, rebellion, and independence, rather than the realities of addiction, suffering, and death.

BOOK

Book reviews and books of interest to “Tobacco Control” should be sent to the editor at the address given on the inside front cover.

Smoke in their eyes

There have been memorable dates, both glorious and infamous, that have defined aims and charted progress and setbacks for the US tobacco control movement. The most notable of these events have had global repercussions.

On 15 December 1953, the heads of four major US tobacco firms met in New York City’s Park Plaza Hotel, where they launched the Tobacco Industry Research Council and hammered out the seminal text of a nationwide newspaper ad, “A frank statement to cigarette smokers”. On 11 January 1964, US Surgeon General Luther Terry released the Report of the Advisory Committee on Smoking and Health, concluding “it is the judgment of the Committee that cigarette smoking contributes substantially to mortality from certain specific diseases and to the overall death rate”. At the Waxman Hearings on 14 April 1994, the “seven dwarves”, chief executive officers (CEOs) of the top seven US tobacco companies, were photographed for posterity as they prepared to declare that “nicotine is not addictive”.

At least one more date marks the US tobacco control calendar, but it evokes no signal image, conjures no immortal quote. And yet, on 3 April 1997, at the Sheraton Hotel in Crystal City, Virginia, an extraordinary meeting did take place. That Thursday afternoon, Geoffrey Bible and Steve Goldstone, CEOs of Philip Morris and RJ Reynolds, respectively, met in secret with trial lawyers and state attorneys general, hoping to hammer out a settlement of litigation pending against the tobacco industry. Along with the CEOs, the lawyers, the attorneys general, and their minions, there was one more participant at that meeting: Matthew Myers, vice president and general counsel of the National Center for Tobacco-Free Kids.

In Smoke in their eyes: lessons in movement leadership from the tobacco wars, Michael Pertschuk describes the political path that led Myers to that Virginia hotel and chronicles what happened in the meeting’s wake. Pertschuk, former head of the US Federal Trade Commission, founder and co-director of the Advocacy Institute, and longtime combatant in the tobacco wars, interviews many key players and makes innovative use of email records to “set the record straight” on the role of various advocates during the tumultuous debate over the 1997 “global” settlement and the 1998 McCain bill. However, as the author repeatedly makes clear, the book is as much an impassioned defence of Myers as it is an analysis of the colossal, scarring failures of tobacco control advocates during that time.

At its core, Smoke in their eyes pits Myers against Stanton Glantz, University of California professor of medicine and lead author of The cigarette papers. For Pertschuk, the plausible, if arguable benefits of the McCain bill could have been realised if not for the schism cleaving former allies into hostile camps. According to Pertschuk, great public health gains could have been realised had Glantz and his zealous followers not frustrated the debate to suit their purposes.

As a behind-the-scenes look at the personalities and polemics of both advocacy groups and political agencies, the book is a rousing success. Though there are few felicitous literary passages, Pertschuk has obtained detailed accounts from former Surgeon General C Everett Koop, former head of the Food and Drug Administration David Kessler, and other principal players, with the glaring exception of Glantz. The book’s central failing, however, is Pertschuk’s unwillingness or inability to focus on Myers’s secret, unilateral decision to attend that first Virginia meeting.

Myers was like Caesar crossing the Rubicon, with just a slight difference or two. Firstly, the general neglected to tell the troops he’d crowned himself emperor. Then, he realised he didn’t know the way to the river’s edge. Those failings are paramount. Myers’ good intentions should not be doubted, but he paved the path to acrimonious, rancorous debate. The Center for Tobacco-Free Kids was not a well established entity in 1997 and many former allies felt betrayed by Myers’ “lone ranger” tactics. Once turned off, they could not easily be convinced to follow Myers anywhere, as demonstrated by the caustic, pitched battles between the rival ENACT and Save Lives, Not Tobacco coalitions.

The what-could-have-beens of the McCain bill are still being debated. The USA is again playing a negative role on the global tobacco stage. This time with respect to the Framework Convention on Tobacco Control. What is certain is that the tobacco industry knew what it wanted back in 1997 and still knows what it wants today.

Philosopher Isaiah Berlin famously borowed the dictum of the Greek poet Archilochus, who wrote: “The fox knows many things, but the hedgehog knows one big thing.” The tobacco industry is a huge, knowing hedgehog. Michael Pertschuk’s insight and intellect help explain how the tobacco control movement has outfoxed itself lately, but his Manichean dichotomy of Myers—good, Glantz—bad does the movement a disservice. The hedgehog rolls along. The fox needs a new game plan.
