ABSTRACT

Background The purpose of this study was to examine attitudes towards attempts to limit second-hand smoke (SHS) in five Eastern European nations.

Methods The data consist of a Eurobarometer (64.3) survey distributed from November to December 2005. Logistic regression was employed to investigate support levels for indoor smoking bans across the five political units.

Results Across nations, there is more support for smoking bans in offices and indoor work spaces and indoor public space as opposed to restaurants and bars and pubs. Personal smoking behaviours are linked strongly with the smoking bans. Most importantly, it is specific knowledge about the health dangers of smoking which fosters support for indoor smoking bans.

Conclusion Policy implications suggest that government and the media must disseminate accurate information about the harm of smoking to broader segments of the population to gain support for policies that affect the dangers of SHS in these nations.

Eastern European nations have higher smoking rates than their Western European neighbours; similarly, countries in the East lag behind the West in implementing smoking bans.\(^1\)\(^{–}\)\(^5\) The purpose of this brief report is to assess support for bans on indoor smoking in five nations with high levels of tobacco use and comparatively few restrictions on limiting second-hand smoke (SHS). These nations are Bulgaria, Croatia, Romania, Turkey and the Turkish Republic of Northern Cyprus.

In Bulgaria, Croatia, Romania and Turkey, there are complete smoking bans in healthcare, education and government facilities. Theatres and cinemas also ban smoking in these nations. The most permissive smoking facilities include pubs and bars. There are no restrictions in Romania and Turkey while Bulgaria and Croatia have partial restrictions. After 6 months of experimentation, Croatia partially eased their smoking ban in cafés in response to complaints from smokers and business owners. There are complete bans in indoor workplaces and offices in Bulgaria and Croatia, but only a partial restriction in Turkey and virtually no restrictions in Romania.\(^6\) Despite these legal restrictions, compliance and enforcement have oftentimes been lax.\(^6\)

METHODS

The data consist of a Eurobarometer (64.3) survey distributed in November to December 2005.\(^7\) In each nation, the sample design consisted of a multistage random probability sample.\(^7\) The survey research teams carried out a comparison between the sample and the universe in each nation. The universe description was based on Eurostat population data or was drawn from national statistical offices. For all countries, the survey team used a national weighting procedure, using marginal and intercellular weighting, based on the universe description. The iteration procedure took into account gender, age and size of locality. We used the STATA V10 subprogram SVY: Logistic (regression) to adjust for the complexities of the sampling design. This allowed the application of sample weights for each nation. While the findings are similar when the weights were not utilised, the weighting procedure resulted generally in more conservative estimates and probability levels for the sample size. Further details on the universe sizes can be obtained.\(^7\) The response rates are as follows: Bulgaria (76.2%), Croatia (49.3%), Romania (91.2%), Turkey (68.7%) and Northern Cyprus (89.8%). For the dependent variables, respondents were asked to express their support for bans on smoking in one of four locations: restaurants; bars or pubs; offices and other indoor workspaces; and any indoor public space such as metros, airports and shops. The specific question is, “Are you in favour of smoking bans in the following places?”

The dependent variable originally consisted of five categories (totally opposed to totally in favour); however, an initial ordered logit analysis did not meet the assumption of parallel regressions as indicated by Brant tests in all equations. Thus, we used a logistic regression analysis where 1=totally in favour or somewhat in favour, and 0=totally opposed, somewhat opposed or don’t know.

For the explanatory variables, we first measured country-specific effects with dummy variables that were created for Bulgaria, Croatia, Northern Cyprus and Turkey (1,0). Romania serves as the reference (comparison) nation. Two binary variables were created for ex-smokers and non-smokers. The reference category is current smokers. Five possible responses (never to often) were utilised to measure how often an individual was bothered by exposure to tobacco smoke in their daily lives. Assertiveness on SHS was measured by a five-category question (also never to often) that queried whether the respondent ever asked a smoker not to smoke because it bothered him/her. Ideology was represented on the left and low values represented the right and low values represented ideology. We captured in a 10-point question where high values represented the right and low values represented the left. Government role legitimacy in health was measured by a five-category question (also never to often) that queried whether the respondent ever felt a government official not to take action because it didn’t benefit him/her. Tobacco control policies were measured by a five-category question (also never to often) that queried whether the respondent ever felt a government official not to take action because it didn’t benefit him/her. Tobacco control policies were measured by a five-category question (also never to often) that queried whether the respondent ever felt a government official not to take action because it didn’t benefit him/her. Tobacco control policies were measured by a five-category question (also never to often) that queried whether the respondent ever felt a government official not to take action because it didn’t benefit him/her.

% Cases correctly classified: SHS, second-hand smoke.

RESULTS

Table 1 lists the percentages of those “totally in favor” or “somewhat in favor” of the smoking bans. Across nations, the greatest level of support for the antismoking measures is found concerning smoking in indoor workplaces and indoor public spaces. There is much less support for smoking bans in restaurants and bars and pubs. Overall, Romania demonstrates the least support for indoor smoking bans except for smoking bans in bars and pubs, where the Croatians are less likely to be supportive.

Table 2 shows the results of the four multivariable logistic regressions. There is evidence of a strong, consistent nation-specific effect, consistent with the results in table 1. Non-smokers and ex-smokers are more amenable than current smokers towards indoor smoking bans, with higher odds ratios for restaurants and bars and pubs.

On three of the four dependent variables, being bothered by SHS was associated with increased support for smoking bans. More important is individual assertiveness concerning SHS; if a respondent would ask a smoker not to smoke, the ORs are from 1.27 to 1.34 times greater that they would support indoor smoking bans of all types.
Ideology was significant only in the case of smoking in offices with those on the right somewhat less likely to support the ban. Those who view government as having a strong role in health are more likely to support the smoking bans across all categories, except for the marginal 0.055 level of significance for indoor spaces. Higher general health was associated with greater support for smoking bans in restaurants and offices.

Knowledge of the general harmful effects of smoking and the negative effects of SHS on pregnancies is strongly and consistently related to increased support for the indoor bans.

The present analysis demonstrates no strong demographic effects, with one exception—age; the older the individual, the greater the support for bans in restaurants and bars.

**DISCUSSION**

The limitations of this study include the fact that the data on smoking behaviour are self-reported. Given that tobacco use is a somewhat sensitive social issue, there may be some imprecision in the responses. In addition, the results can be generalised only to the nations included in this study, which have a history of high tobacco consumption.

Notwithstanding these limitations, the findings have important implications for policy and practice. First, although smoking is a huge public health problem among these nations, there are important differences in support. Romania has the largest problem in attaining acceptance of the bans. With the exception of Croatia in the case of bars and pubs, support for the indoor bans is stronger across every nation and for each dependent variable. Nonetheless, it is important to note that there was major support in each country for bans in restaurants, bars and pubs, indoor workspaces, and indoor public places (the only exception being support for smoke-free bars and pubs among Croatians), and the support was greater than 70% in 13 of the 20 combinations of locations and country (see table 1). These findings should be advertised to the general population, and to policy makers and other key opinion leaders.

Second, as has been well-documented in the literature, individuals’ attitudes are associated with their own smoking behaviour. Smokers are less supportive of bans that limit their behaviour. Those who reported better health in general are more supportive of smoking bans. Further, younger respondents are less likely to support smoking bans than older respondents. The best potential for increasing support for indoor smoking bans appears to be respondents learning about the harmful effects of SHS. The analysis has demonstrated that individuals who know about the harmful effects of SHS are more apt to support bans on indoor smoking than others. Media and government must disseminate accurate information on the health effects of SHS if there are to be substantial changes in behaviour. Current efforts include those by the World Health Organization in these nations that encourage utilisation of primary care providers, advocate strong leadership in community and government organisations, and media campaigns to relay information that will increase knowledge and decrease smoking. This information will continue to compete against strong cultural norms that encourage smoking in these Eastern European nations.
